1.1.1 Abstract

The building construction industry faces challenges, such as increasing project complexity, and scope requirements but shorter deadlines. Additionally, the industry relies on practices based on intuition and experience, overlooking the dynamics of its production system. These approaches underestimate the influence of process repetitiveness, the size of the production run, the transient state (setup times), the variation of learning curves, and the conservation of processes properties. Consequently, construction adopts the manufacturing production model dismissing the application of mathematical approaches that accurately describe the characteristics of its production system. This chapter aims to provide a production theory to describe and understand the production mechanisms of repetitive processes in project-driven systems in construction. The chapter begins with an examination of the existing knowledge about production models, their characteristics, and the challenges to establishing a theoretical framework for controlling dynamic production systems management in construction projects. The chapter progresses to an analytical and scalable method (Productivity Function) to represent the behavior of production systems. The Productivity Function provides a mathematical foundation to develop algebraic for the calculations of cycle times (average, best- and worst-cases), throughput at capacity, and the influence of the transient state time in the production variability. Productivity Function is applied in feedback loop control yielding a robust approach to plan, control, and optimize production. Finally, the chapter presents automatic methods of data collection that feed the Productivity Function models, which are the foundation of the production theory and support the decision-making process on Lean Construction 4.0.

1.1.2 Outline

1. Introduction
2. Lean principles and production theory
 - (a) Production in Manufacturing (Factory Physics)
 - (b) The manufacturing theory does not apply directly to construction
3. Productivity Function
 - (a) Process system representation
 - (b) Mathematical foundation
 - (c) Modelling method

- 4. Production Theory
 - (a) Decision-making support and production forecast
 - (b) Variability analysis
 - (c) Production benchmark
 - i. Capacity
 - ii. Throughput
 - iii. Cycle-time
 - A. Average cycle-time
 - B. Worst cycle-time
 - C. Best cycle-time
 - (d) Production plan, monitoring, and control
- 5. Applicability
 - (a) Automation and technology
 - i. Supervisory control and data acquisition (SCADA)
 - ii. Challenges
 - (b) Decision-making support
 - (c) Benefits and impacts
- 6. Discussion
- 7. Conclusion
